populating and querying?

01

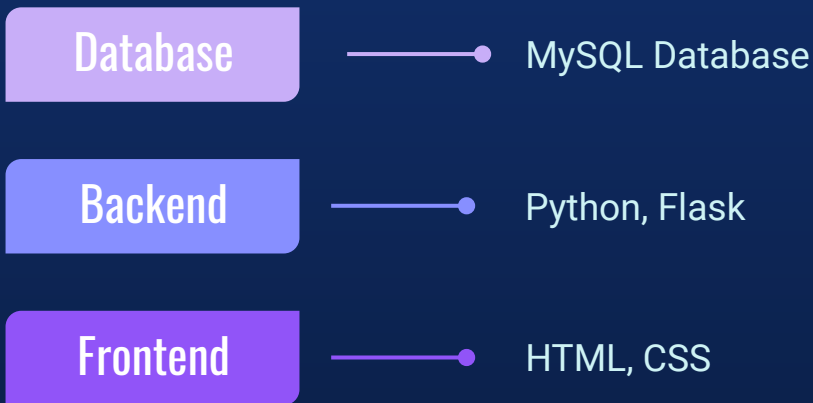

Project Overview

What is Foogle?

Foogle is a search engine aggregator, which compiles the results from other widely used search engines, stores the results into a mySQL database, and then displays the most relevant results by keyword to the consumer.

THEM VS US

THEM

- Search Engine companies are ultimately for-profit organizations
- Ranking algorithms are often business driven
- Ads are given priority

Foogle

- Utilize word frequency instead of ranking algorithms
 - Ads are filtered
 - Refined secondary searches from resultant first set of searches
-

ckgo-private-search](https://help.duckduckgo.com/duckduckgo-help-pages/company/ads-by-microsoft-on-duckduckgo-private-search)
- [https://duckduckgo.com/y.js?ad_domain'](https://duckduckgo.com/y.js?ad_domain)

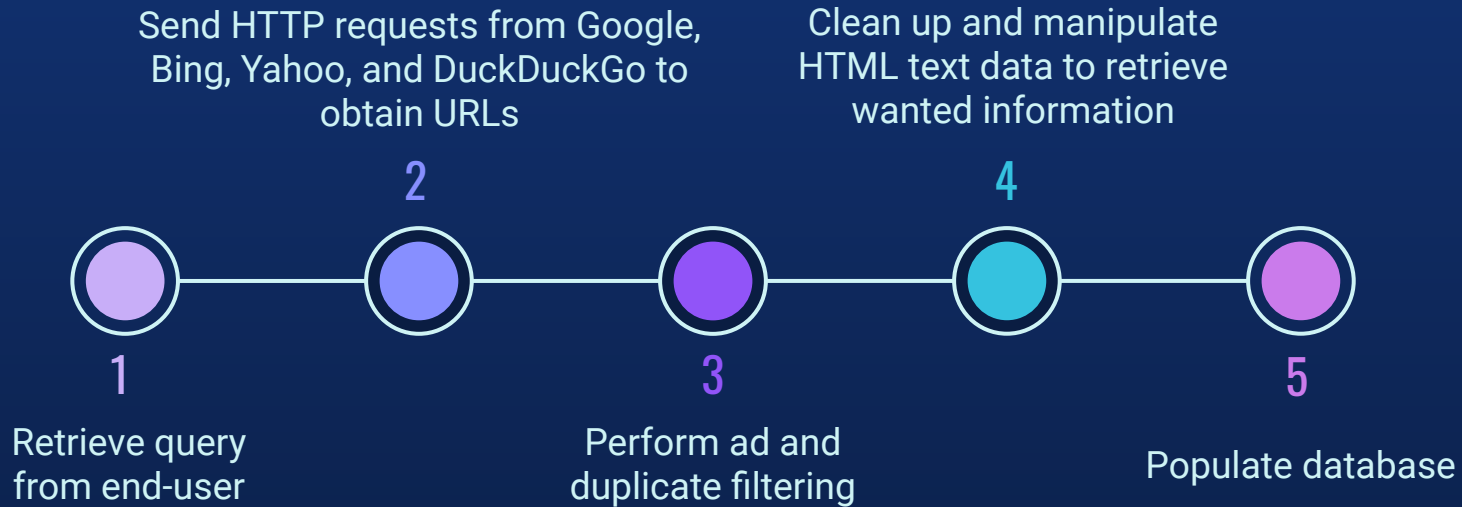

Populate Database Process

Python BeautifulSoup

Populate Database Process

Python MySQL Connector

Query Database Process

Retrieve websites from database based on the end-user query relevance with the text from the URL

**mySQL Natural Language
Full-Text Search**

Query Database Process

Python NLTK

Retrieve keywords from the end-user query by removing stopwords

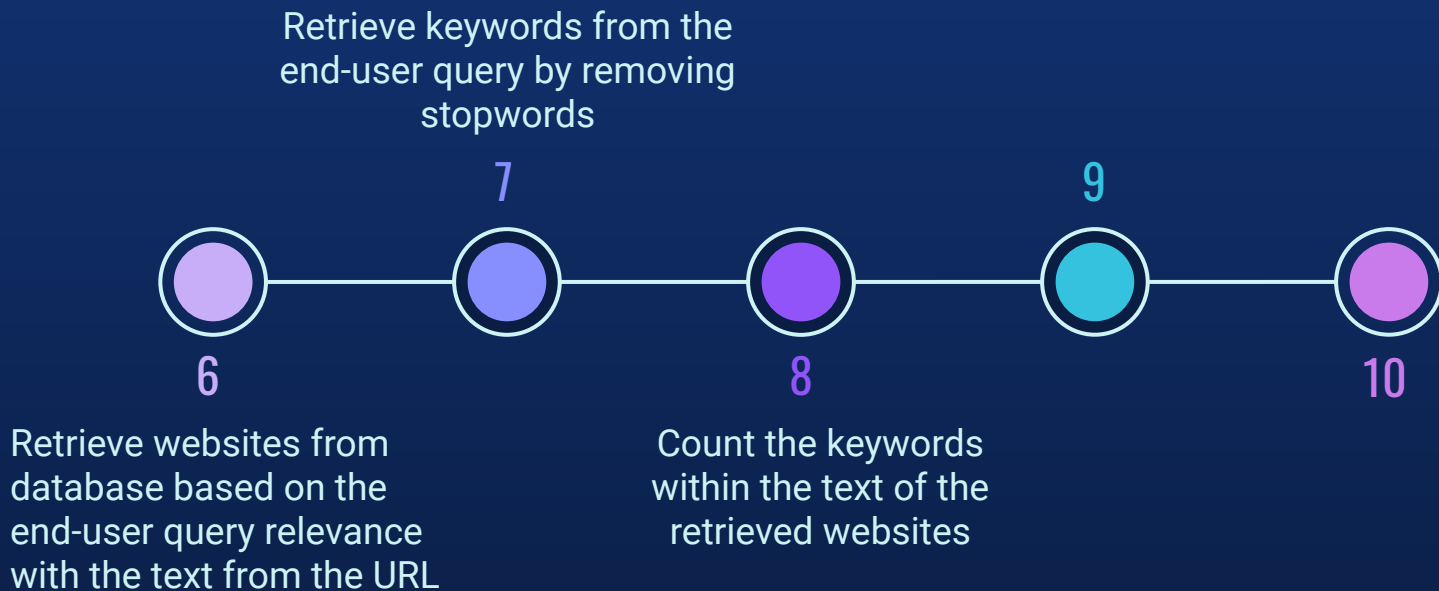

Retrieve websites from database based on the end-user query relevance with the text from the URL

Query Database Process

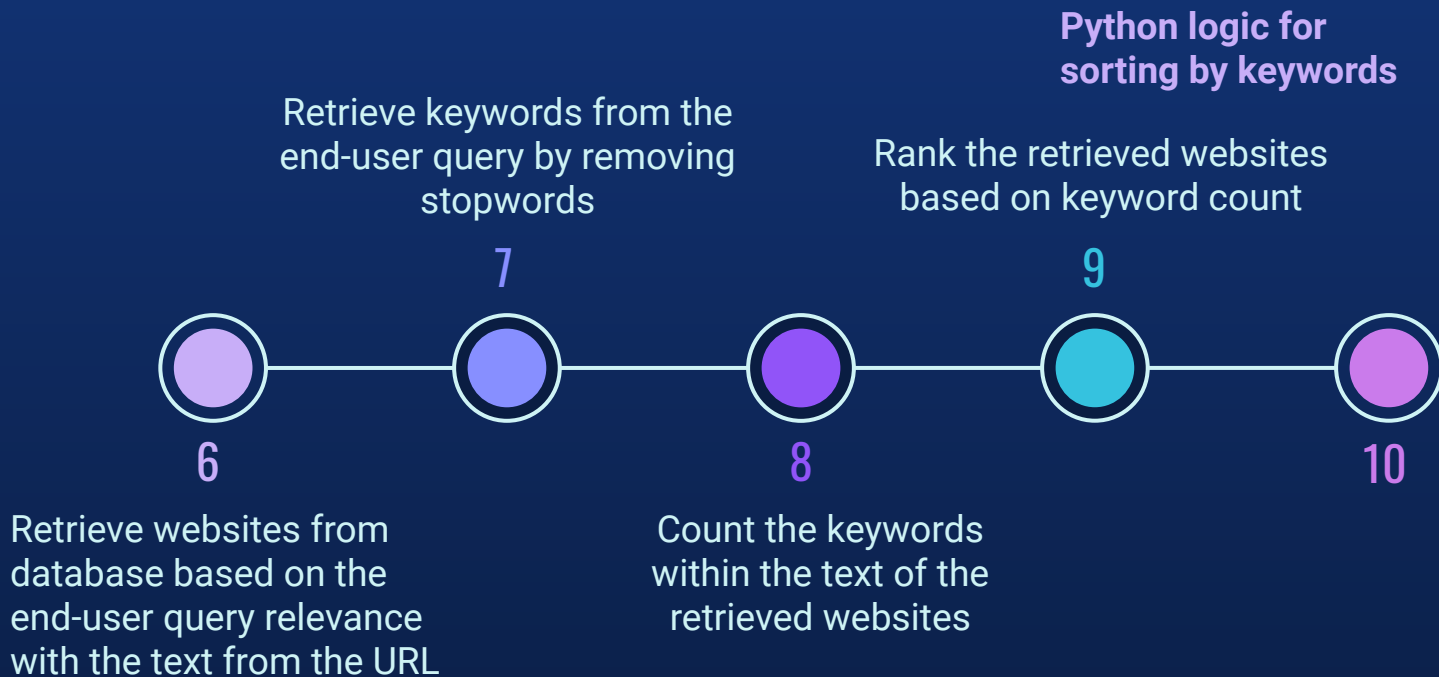

Python Collections

Query Database Process

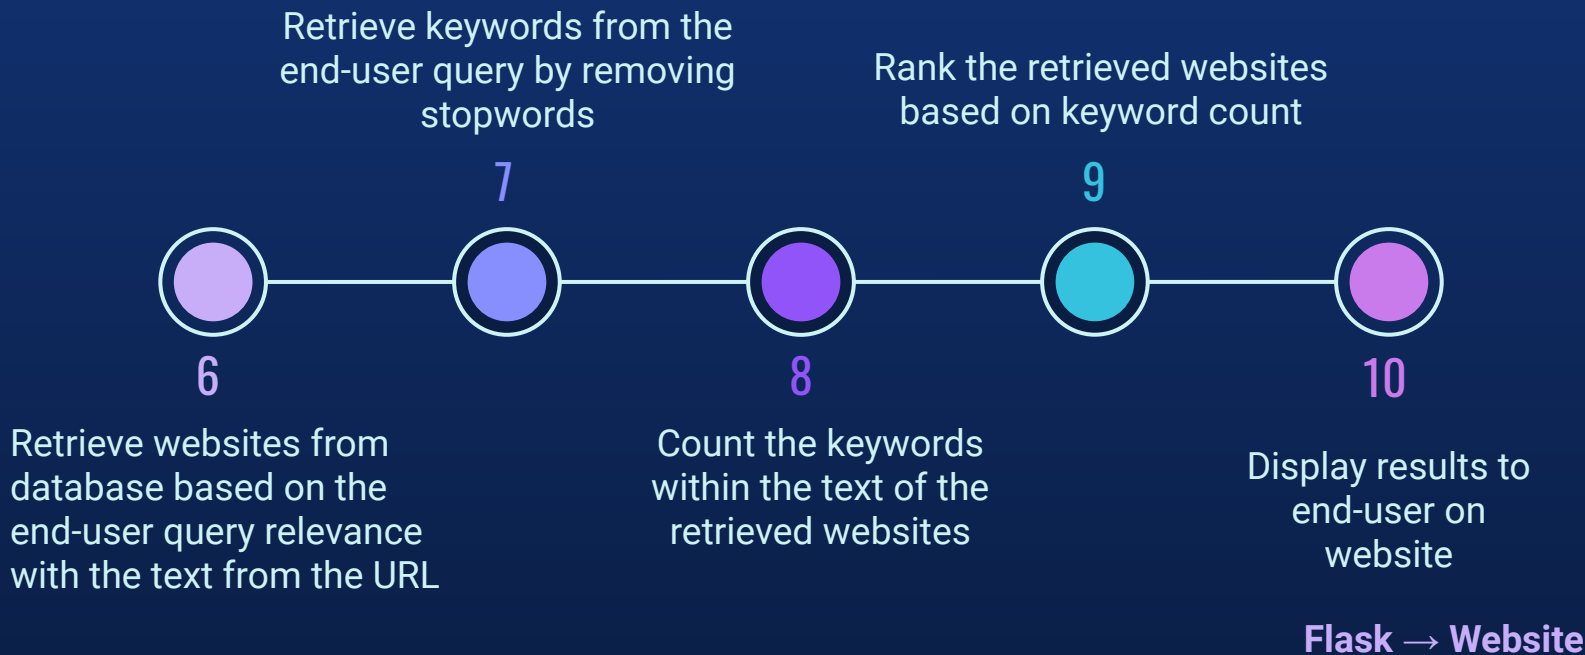

Keyword Ranking Algorithm

- Remove stop words from input query to get a list of keywords
- Use Python's Collection Library to count the number of keywords in each website resulted from MySQL Natural Language Full-Text Search
- Sum the total number of keyword counts for each resultant website
- Display the website results based on keyword count, in descending order

Query Database Process
